Master Thesis

# Stabilizing Global Simulation in GKW by the Introduction of the Parallel Electric Field $E_{\parallel}$

Manuel Lippert

Submission date: December 12, 2023

Physics Department at the University of Bayreuth

Supervisors:

Prof. Arthur G. Peeters

Dr. Florian Rath

★ 07.07.2020

This thesis is dedicated to my cat **Leo**  
who is part of our family since July 2020.  
He is the kindest cat I ever own and very playful.  
For a long life together.

I love you.

Manuel Lippert

# Derivation Gyrokinetic Equations and Inductive Electric Field $E_{||}$

# 1

## 1.1 Charged Particle Motion in Magnetic and Electric Field

In magnetic confinement devices like the tokamak reactor, the charged particles experience forces caused by magnetic and electric fields which results in distinct motion under the associated force. Charged particles can be separated in species, e.g. electrons and ions, which will be later on not displayed in the governing equation. Throughout this thesis the charge  $q$ , the mass  $m$  or the temperature  $T$  indicate the quantities of a specific species, i.e., electrons or ions.

### 1.1.1 Particle Motion perpendicular to the magnetic field

Due to the Lorentz force, particles with a velocity component perpendicular to the homogenous magnetic field  $v_{\perp}$  undergo a circular motion in the plane perpendicular to the magnetic field [Fig. 1.1(a)]. This type of motion has circular frequency, which is often referred to as *cyclotron frequency* and is defined as

$$\omega_c = \frac{|q|B}{m} , \quad (1)$$

where  $m$  and  $q$  are the mass and the charge of the particle and  $B$  the strength of the magnetic field. The radius, the so called *Larmor radius*, of this motion is given by

$$\rho = \frac{mv_{\perp}}{|q|B} \quad (2)$$

with the center often being referred to as *gyrocenter*. Note that since the Lorentz force depends on the species charge of the particle, the circulation direction is the opposite between electron in ions.

Due to Coulomb collisions the plasma gets thermalized. Together with the Maxwell-Boltzmann distribution the typical thermal velocity is

$$v_{\text{th}} = \sqrt{\frac{2T}{m}} , \quad (3)$$

where  $T$  represents the species temperature. Based on the thermal velocity  $v_{\text{th}}$  the *thermal Larmor radius* gets introduced as<sup>10</sup>

$$\rho_{\text{th}} = \frac{mv_{\text{th}}}{|q|B} . \quad (4)$$

### 1.1.2 Particle Motion parallel to the magnetic field

In absence of forces in the direction parallel to the magnetic field the particles can move freely in parallel direction to the homogenous magnetic field. The velocity of this motion is of order of the thermal velocity  $v_{th}$  and is dominated by electrons due to their lighter mass compared to ions ( $v_{th,e}/v_{th,i} = 60$ ).

When an electric field with a component parallel to the magnetic field  $E_{\parallel}$  influences the plasma the charged particles are accelerated by the electric force

$$F_{\parallel,E} = qE_{\parallel} . \quad (5)$$

The parallel motion follows then from the equation of motion. Here the direction of the motion also depends on the species type [Fig. 1.1(b)].

Since magnetic fields are not always homogenous, an inhomogeneous magnetic field with its gradient  $\nabla B$  containing a component parallel to the magnetic field which is given by

$$\nabla_{\parallel} B = \frac{\mathbf{B}}{B} \cdot \nabla B \quad (6)$$

causes the force

$$F_{\parallel,\nabla B} = -\frac{mv_{\perp}^2}{2B} \nabla_{\parallel} B = -\mu \nabla_{\parallel} B ; \quad \mu = \frac{mv_{\perp}^2}{2B} \quad (7)$$

with *magnetic moment*  $\mu$ . The magnetic moment  $\mu$  is an adiabatic invariant (constant of motion) if the variation of the magnetic field over time is smaller than the inverse of the cyclotron frequency  $\omega_c^{-1}$  and the spatial variation is larger the Larmor radius  $\rho_L$ . The resulting force has its application in the mirror effect where a charged particle gets reflected due to this force [Fig. 1.1(c)].<sup>10</sup>

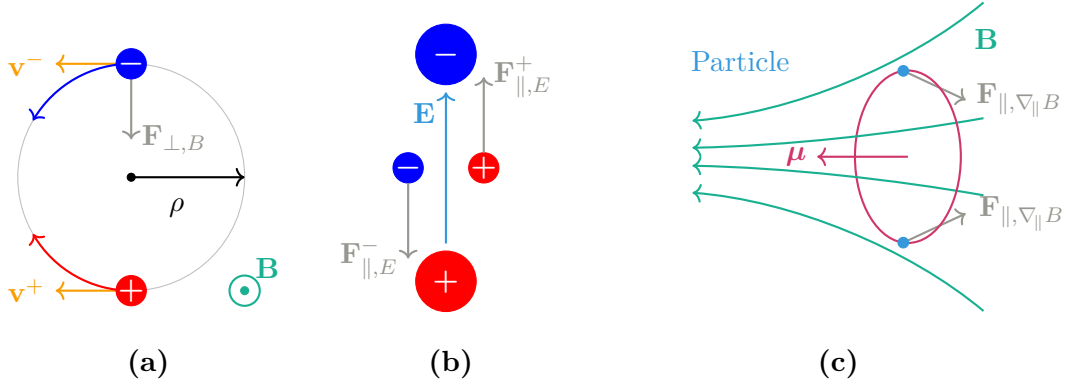

Figure 1.1: Forces acting on a charged particle:

- (a) Lorentz force  $\mathbf{F}_{\perp, B}$  perpendicular to velocity  $\mathbf{v}^{\pm}$  and magnetic field  $\mathbf{B}$  which causes, circular motion with different directions for electron and ions, Larmor radius  $\rho_L$  and cyclotron frequency  $\omega_c$ ,
- (b) Electric force  $\mathbf{F}_{\parallel, E}^{\pm}$  with electric field  $\mathbf{E}$ ,
- (c) Mirror effect with force  $\mathbf{F}_{\parallel, \nabla_{\parallel} B}$  and magnetic moment  $\mu$  caused by an inhomogeneous magnetic field  $\mathbf{B}$ .

### 1.1.3 Drifts in the Gyrocenter

In the presence of a magnetic field (homogenous, inhomogeneous or perturbed) and electric fields the gyrocenter undergoes slow (compared to the thermal velocity  $v_{th}$ ) drift motions perpendicular to the magnetic field. There are several examples for this drift motion. According to this thesis topic only the main three drift types will be covered in the following.

1.  **$\mathbf{E} \times \mathbf{B}$  Drift:**

If an electric field  $\mathbf{E}$  with a perpendicular component together with the magnetic field  $\mathbf{B}$  (both fields are homogenous) is present the acting Coulomb force and Lorentz force results into a drift of the gyrocenter with

$$\mathbf{v}_E = \frac{\mathbf{E} \times \mathbf{B}}{B^2} \quad (8)$$

which is called the  $\mathbf{E} \times \mathbf{B}$  drift. Since both acting forces direction depends on the species type the direction of the  $\mathbf{E} \times \mathbf{B}$  drift is for every species the same [Fig. 1.2(a)].

2.  **$\nabla B$  Drift:**

Inhomogeneous magnetic field causes a gradient  $\nabla B$  of the magnetic field. Because of that gradient the gyrocenter undergoes a  $\nabla B$  drift defined by

$$\mathbf{v}_{\nabla B} = \frac{mv_{\perp}^2}{2q} \frac{\mathbf{B} \times \nabla B}{B^3} . \quad (9)$$

The gradient of the magnetic field  $\nabla B$  varies thereby on scales larger compared to the Larmor radius. The direction of the  $\nabla B$  drift depends on the species type [Fig. 1.2(b)].

3. **Curvature Drift:**

Due to centrifugal force acting on the particle in a curved magnetic field the gyrocenter experiences a curvature drift according to

$$\mathbf{v}_C = \frac{mv_{\parallel}^2}{q} \frac{\mathbf{B} \times \mathbf{C}}{B^2} = \frac{mv_{\parallel}^2}{q} \frac{\mathbf{B} \times \nabla B}{B^3} ; \quad \mathbf{C} = -(\mathbf{b} \cdot \nabla)\mathbf{b} = \frac{\nabla B}{B} , \quad (10)$$

where  $\mathbf{b}$  is the unit vector along the magnetic field. To obtain the result for the curvature  $\mathbf{C}$  in Eq. (10) the plasma pressure has to be small compared to the magnetic field strength  $B$ . In the form of Eq. (10)  $\nabla B$  and curvature drift can be treated similarly.<sup>10</sup>

Figure 1.2: Drift motion in gyrocenter:

- (a)  $\mathbf{E} \times \mathbf{B}$  Drift with drift velocity  $\mathbf{v}_E$ , electric field  $\mathbf{E}$  and magnetic field  $\mathbf{B}$ ,
- (b)  $\nabla B$  Drift/Curvature Drift with drift velocity  $\mathbf{v}_{\nabla B;C}^{\pm}$ , magnetic field  $\mathbf{B}$  and gradient of the magnetic field  $\nabla B$ .

## 1.2 Magnetic Confinement and Plasma Rotation

In tokamak devices strong magnetic fields confine the hot plasma. As mentioned in Chapter 1.1 a magnetic field forces a perpendicular particle motion and a motion which contains the gyro motion and slow perpendicular gyro center drifts. Because of the much smaller size of the Larmor radius compared to the device size  $R$  the particle and energy losses are caused by the gyro center drift. To avoid additional loss of particles because of the parallel motion the field lines of the magnetic field in the tokamak devices is shaped like a torus. This type of geometry has nested surfaces with constant magnetic flux, so-called *flux surfaces*, and magnetic field lines which lie on these surfaces. To maintain stability the magnetic field has a toroidal and a poloidal component. According to the force balance the magnetic field is equivalent to the plasma pressure which means on flux-surfaces the plasma pressure is constant.<sup>8,10</sup> The toroidal component is produced by external coils whereas the poloidal component is provided by the toroidal plasma current. Together the components result in a magnetic field which follows helical trajectories [Fig 1.3]. To characterize the quality of confinement the so-called *plasma beta* is used and is given as

$$\beta = \frac{nT}{\mu_0 B^2/2}, \quad (11)$$

with  $n$  the plasma density,  $T$  as temperature,  $\mu_0$  the permeability in vacuum and the magnetic field strength  $B$ . Respectively, the plasma beta compares the thermal plasma pressure  $nT$  to the ambient magnetic field pressure  $\mu_0 B^2/2$ . For fusion devices the plasma beta has to be a bit smaller than 1 ( $\beta < 1$ ) for optimal confinement. In a tokamak reactor the plasma beta has a typical order of a few percent.<sup>10</sup>

Figure 1.3: Toroidal flux surfaces in tokamak plasma with helical magnetic field (green line) in torus coordinates ( $\rho$  (radial),  $\phi$  (toroidal),  $\theta$  (poloidal)) or cylindrical coordinates ( $Z, R, \phi$ ).<sup>1</sup>

The rotation of the plasma can be described in a co-rotating frame of reference, which is rigidly rotating with the velocity  $\mathbf{u}_0$  and will be used later on in the derivation of the gyrokinetic equations in Chapter 1.4. It is assumed that the poloidal component of the plasma rotation is much smaller compared to the toroidal component and will be neglected. With this assumption in mind the reference frame is chosen to move in the toroidal direction exclusively and its velocity  $\mathbf{u}_0$  can be expressed as

$$\mathbf{u}_0 = \mathbf{\Omega} \times \mathbf{x} = R^2 \Omega \nabla \varphi , \quad (12)$$

where  $\mathbf{\Omega}$  is the constant angular frequency,  $\varphi$  is the toroidal angle and  $R \nabla \varphi$  is the unit vector in the toroidal direction. Since the rotation of the plasma in the laboratory frame is not a rigid body rotation, it will be characterized by the radial profile of the angular velocity  $\hat{\Omega}(\psi)$ . Then the angular frequency of the rotating frame  $\Omega$  is chosen to match the plasma rotation on a certain point, i.e.  $\Omega = \hat{\Omega}(\psi_r)$ . The plasma rotation in the co-rotating frame of reference will be denoted as

$$\omega_{\varphi}(\psi) = \hat{\Omega}(\psi) - \Omega. \quad (13)$$

with the rotation speed along the magnetic field line

$$u_{\parallel} = \frac{R B_t}{B} \omega_{\varphi}(\psi) , \quad (14)$$

where  $B_t$  is the toroidal component of the magnetic field.<sup>7</sup>

### 1.3 Gyrokinetic Ordering

In the derivation of the gyrokinetic theory the aim is to decouple the effect of small-scale, small amplitude fluctuations of the plasma in the Langrangian. For this it is chosen to take the properties of fluctuations as small parameter, which will get in the ordering assumptions applied in gyrokinetic theory<sup>2</sup>

$$\begin{aligned}
 \frac{|\mathbf{A}_1|}{|\mathbf{A}_0|} &\sim \frac{\Phi_1}{\Phi_0} \sim \epsilon_{\delta} \ll 1 \\
 \rho \frac{\nabla B_0}{B_0} &\sim \rho \frac{\nabla E_0}{E_0} \sim \frac{\rho}{L_B} \sim \epsilon_B \ll 1 \\
 k_{\perp} \rho &\sim \epsilon_{\perp} \sim 1 \\
 \frac{\omega}{\omega_c} &\sim \epsilon_{\omega} \ll 1
 \end{aligned} \tag{15}$$

where  $\mathbf{A}$  and  $\Phi$  are the vector and scalar potentials,  $\mathbf{B}$  and  $\mathbf{E}$  are the magnetic and electric fields,  $\omega$  and  $k_{\perp}$  are the typical mode frequency and perpendicular wavenumber defined as  $k_{\perp} = |\mathbf{k} \times \mathbf{b}|$ ,  $\rho$  and  $\omega_c$  are the Larmor radius and cyclotron frequency and  $L_B$  the equilibrium magnetic length scale. The equilibrium quantities are denoted with 0 and the fluctuations with 1 subscript.

The above-mentioned equations state that fluctuations have a much smaller magnitude than the corresponding equilibrium values, their typical timescale is much slower than the Larmor frequency, their characteristic length scale is of the order of the Larmor radius, and it is typically much shorter the equilibrium spatial variation scale. Teh gyrokinetic equations are valid under these ordering assumptions.

The small parameters  $\epsilon_{\delta}$ ,  $\epsilon_B$ ,  $\epsilon_{\perp}$  and  $\epsilon_{\omega}$  are due to different physical but in practice it is assumed that they are of similar order and substitute them with one parameter. For the derivation of the gyrokinetic equations of GKW all derived equations are evaluated up to the first order of the ratio of the reference thermal Larmor radius  $\rho_{\text{th,ref}}$  and the equilibrium magnetic length scale  $L_B$  as small parameter and is defined as<sup>9</sup>

$$\rho_{\star} = \frac{\rho_{\text{th,ref}}}{L_B} = \frac{m_{\text{ref}} v_{\text{th,ref}}}{e B_{\text{ref}}} \sim \epsilon_B \sim \epsilon_{\delta} \sim \epsilon_{\omega} . \tag{16}$$

## 1.4 Gyrokinetic Lagrangian (Fundamental One-Form)

### 1.4.1 Lagrangian in Particle Phase Space

The Lagrangian of a particle  $\gamma$  with mass  $m$  and charge number  $Z$  in the electro magnetic field will be described through the particle position  $\mathbf{x}$  and the velocity  $\mathbf{v}$  as coordinates  $\{\mathbf{x}, \mathbf{v}\}$  and can be written as

$$\gamma = \gamma_{\nu} dz^{\nu} = \underbrace{(m\mathbf{v} + Ze\mathbf{A}(\mathbf{x})) \cdot d\mathbf{x}}_{\text{Symplectic Part}} - \underbrace{\left(\frac{1}{2}mv^2 + Ze\Phi(\mathbf{x})\right) dt}_{\text{Hamiltonian } H(\mathbf{x}, \mathbf{v})}, \quad (17)$$

where  $\mathbf{A}$  and  $\Phi$  are the vector and scalar potential,  $\nu$  indexes the six coordinates, and Einstein notation is applied. This form is also known as fundamental one-form.

The defined Lagrangian  $\gamma$  will then be transformed in the rotating frame of reference [Ch. 1.2], which can be achieved the following Lorentz transformation

$$\mathbf{v} \rightarrow \mathbf{v} + \mathbf{u}_0 \quad \mathbf{E} \rightarrow \mathbf{E} + \mathbf{u}_0 \times \mathbf{B} \quad \Phi \rightarrow \Phi + \mathbf{A} \cdot \mathbf{u}_0. \quad (18)$$

After performing the transformation outlined in Ref. 7 the Lagrangian  $\gamma$  becomes

$$\gamma = (m\mathbf{v} + m\mathbf{u}_0 + Ze\mathbf{A}(\mathbf{x})) \cdot d\mathbf{x} - \left(\frac{1}{2}mv^2 - \frac{1}{2}mu_0^2 + Ze\Phi(\mathbf{x})\right) dt. \quad (19)$$

In the next step small scale perturbations of the electromagnetic field gets introduced as following

$$\mathbf{A} = \mathbf{A}_0 + \mathbf{A}_1 \quad \Phi = \Phi_0 + \Phi_1. \quad (20)$$

Here, it is assumend that the equilibrium electric field is zero in a stationary plasma, but it will be kept in case for finite plasma rotation. According to the gyrokinetic ordering [Ch. 1.3] the perturbations are in the first order of  $\rho_{\star}$ . Taking everything into account the Lagrangian in the particle phase space with perturbations can be written as

$$\begin{aligned} \gamma &= \gamma_0 + \gamma_1 \\ \gamma_0 &= (m\mathbf{v} + m\mathbf{u}_0 + Ze\mathbf{A}_0(\mathbf{x})) \cdot d\mathbf{x} - \left(\frac{1}{2}mv^2 - \frac{1}{2}mu_0^2 + Ze\Phi_0(\mathbf{x})\right) dt \\ \gamma_1 &= Ze\mathbf{A}_1(\mathbf{x}) \cdot d\mathbf{x} - Ze\Phi_1(\mathbf{x}) dt. \end{aligned} \quad (21)$$

### 1.4.2 Lagrangian in Guiding Center Phase Space

For the description of charged particle behaviour in the tokamak device the *guiding center coordinates* are used [Fig. 1.4]. This set of coordinates are defined as the following

$$\begin{aligned} \mathbf{X}(\mathbf{x}, \mathbf{v}) &= \mathbf{x} - \rho(\mathbf{x}, \mathbf{v})\mathbf{a}(\mathbf{x}, \mathbf{v}) & v_{\parallel} &= \mathbf{v} \cdot \mathbf{b}(\mathbf{x}) \\ \mu(\mathbf{x}, \mathbf{v}) &= \frac{mv_{\perp}^2(\mathbf{x})}{2B(\mathbf{x})} & \theta(\mathbf{x}, \mathbf{v}) &= \arccos\left(\frac{1}{v_{\perp}}(\mathbf{b}(\mathbf{x}) \times \mathbf{v}) \cdot \hat{\mathbf{e}}_1\right), \end{aligned} \quad (22)$$

where the guiding center follows the magnetic field with the parallel velocity  $v_{\parallel}$ . The gyromotion is described together with the magnetic moment  $\mu$ , the guiding center  $\mathbf{X}$  and the gyro phase  $\theta$  which gives a parameter set of six quantities  $\{\mathbf{X}, v_{\parallel}, \mu, \theta\}$ . Vector  $\mathbf{b}(\mathbf{x})$  is the unit vector in the direction of the equilibrium magnetic field and  $\rho(\mathbf{x}, \mathbf{v})\mathbf{a}(\mathbf{x}, \mathbf{v})$  is the vector pointing from the guiding center to the particles position, which is defined by the unit vector  $\mathbf{a}(\mathbf{x}, \mathbf{v})$  and its length is the Lamor radius  $\rho(\mathbf{x}, \mathbf{v})$ . The unit vector  $\mathbf{a}(\mathbf{x}, \mathbf{v})$  can be expressed in a local orthonormal basis as the function of the gyroangle  $\theta$

$$\mathbf{a}(\theta) = \hat{\mathbf{e}}_1 \cos \theta + \hat{\mathbf{e}}_2 \sin \theta. \quad (23)$$

The vectors  $\mathbf{b}$ ,  $\hat{\mathbf{e}}_1$  and  $\hat{\mathbf{e}}_2$  form a local Cartesian coordinate system at the guiding center position.

Figure 1.4: Sketch of guiding center coordinates where the charged particle performs a circular motion around the guiding center.<sup>6</sup>

To transform the fundamental one-form into the guiding center coordinates the following relation will be used

$$\Gamma_{\eta} = \gamma_{\nu} \frac{dz^{\nu}}{dZ^{\eta}} , \quad (24)$$

where  $\Gamma_{\eta}$  is a component of the guiding center fundamental one-form. To calculate the new coordinates the transformation [Eq. (22)] have to be inverted to provide the old coordinates as function of the new one  $z(Z)$ . Here, the direct transformation is clearly uniquely determined if the magnetic field is known at the particle position. However, the inverse transformation is not uniquely due to the dependence of the Larmor radius  $\rho$  on magnetic field at the particle position  $\mathbf{x}$ . Taylor expansion of the Larmor radius  $\rho$  around the guiding center  $\mathbf{X}$  yields  $\rho(\mathbf{x}) \approx \rho(\mathbf{X})$ . Note, that terms of order  $\rho^2$ , which leads to second order terms in  $\rho_{\star}$ , will get neglected due to the gyrokinetic ordering. The Larmor radius  $\rho$  also depends on the velocity  $\mathbf{v}$  in particle phase space [Eq. (2)], or the magnetic moment  $\mu$  in the guiding center phase space through the formular

$$\rho(\mathbf{X}, \mu) = \frac{1}{Ze} \sqrt{\frac{2\mu m}{B(\mathbf{X})}} . \quad (25)$$

This dependence will be only used if greater clarity is needed. With result of the Taylor expansion the particle position  $\mathbf{x}$  can be expressed with the guiding center coordinates as

$$\mathbf{x}(\mathbf{X}, \theta) \approx \mathbf{X} + \rho(\mathbf{X}) \mathbf{a}(\theta) . \quad (26)$$

The particle velocity  $\mathbf{v}$  is the sum of the velocity along the magnetic field  $v_{\parallel}$ , the gyration velocity  $\mathbf{v}_{\perp}$  and the drift velocity, which will be neglected because the particle drifts can be described by the motion of the guiding center. So to summarize the velocity  $\mathbf{v}$  in the guiding center frame can be expressed as

$$\mathbf{v} = v_{\parallel} \mathbf{b}(\mathbf{x}) + \mathbf{v}_{\perp} = v_{\parallel} \mathbf{b}(\mathbf{x}) + \rho(\mathbf{x}) \dot{\mathbf{a}}(\theta) . \quad (27)$$

Applying Taylor expansion again around the guiding center  $\mathbf{X}$  the following expression can be obtained

$$\mathbf{v}(\mathbf{X}, v_{\parallel}, \mu, \theta) \approx v_{\parallel} [\mathbf{b}(\mathbf{X}) + \partial_{\mathbf{X}} \mathbf{b}(\mathbf{X}) \cdot \mathbf{a}(\theta) \rho(\mathbf{X}, \mu)] + \rho(\mathbf{X}, \mu) \dot{\mathbf{a}}(\theta) . \quad (28)$$

Now, the transformation [Eq. (24)] can be applied to express the fundamental one-form in the new coordinates with the following components

$$\begin{aligned} \Gamma_{X^i} &= \gamma_{x^j} \frac{dx^j}{dX^i} + \gamma_{v^j} \frac{dv^j}{dX^i} + \gamma_t \frac{dt}{dX^i} = \gamma_{x^j} \frac{dx^j}{dX^i} & \Gamma_{v_{\parallel}} &= \gamma_{x^j} \frac{dx^j}{dv_{\parallel}} + \gamma_{v^j} \frac{dv^j}{dv_{\parallel}} = 0 \\ \Gamma_{\mu} &= \gamma_{x^j} \frac{dx^j}{d\mu} & \Gamma_{\theta} &= \gamma_{x^j} \frac{dx^j}{d\theta} \\ \Gamma_t &= \gamma_t \frac{dt}{dt} + \mu B(\mathbf{X}) = \gamma_t + \mu B(\mathbf{X}) . \end{aligned} \quad (29)$$

Note, that to the Hamiltonian part  $\Gamma_t$  the energy term of the magnetic field  $B$  at the guiding center  $\mathbf{X}$  has to be added, due to the circular motion of the particle around the center.

In Equation (29) the components of the fundamental one-form of the particle phase space  $\gamma_{\nu}$  and the equation for  $\mathbf{v}$  in guiding center coordinates [Eq. (28)] will be inserted and the Taylor expansion up to the first order applied for terms containing the particle position  $\mathbf{x}$  as argument. After that the gyroaveraging operator will be used, which is defined as the integral over the gyrophase  $\theta$

$$\langle \cdot \rangle = \frac{1}{2\pi} \int_0^{2\pi} (\cdot) d\theta . \quad (30)$$

Due to the definition of the vector  $\mathbf{a}$  [Eq. (23)] the first order terms in  $\mathbf{a}$  and  $\dot{\mathbf{a}}$  disappear under gyroaveraging. Following all the previous steps, one can obtain

$$\begin{aligned} \langle \Gamma_{\mathbf{X}} \rangle &= mv_{\parallel} b_i(\mathbf{X}) + mu_{0i} + Ze\mathbf{A}(\mathbf{X}) & \langle \Gamma_{v_{\parallel}} \rangle &= 0 \\ \langle \Gamma_{\mu} \rangle &= 0 & \langle \Gamma_{\theta} \rangle &= \frac{2\mu m}{Ze} \\ \langle \Gamma_t \rangle &= - \left( \frac{1}{2}mv_{\parallel}^2 - \frac{1}{2}mu_0^2 + Ze\Phi(\mathbf{X}) + \mu B(\mathbf{X}) \right) , \end{aligned} \quad (31)$$

which results in the fundamental one-form in guiding center coordinates

$$\begin{aligned} \langle \Gamma \rangle &= (mv_{\parallel} \mathbf{b}(\mathbf{X}) + m\mathbf{u}_0 + Ze\mathbf{A}(\mathbf{X})) \cdot d\mathbf{X} + \frac{2\mu m}{Ze} d\theta \\ &\quad - \left( \frac{1}{2}mv_{\parallel}^2 - \frac{1}{2}mu_0^2 + Ze\Phi(\mathbf{X}) + \mu B(\mathbf{X}) \right) dt . \end{aligned} \quad (32)$$

Note that as a consequence of the Lagrangian being independent of the gyrophase  $\theta$ , the magnetic moment  $\mu$  (the associated conjugated coordinate pair of  $\theta$ ) becomes an invariant of the motion ( $\dot{\mu} = 0$ ).

As in Chapter 1.4.1 perturbations [Eq. (20)] will get introduced to the guiding center Lagrangian. The transformation of the equilibrium part is already performed above, so only the perturbation part with the perturbed Lagrangian in the particle phase space  $\gamma_1$  has to be transformed to the guiding center phase space. The transformation is analogous to the calculation before, the key difference is that the fluctuations quantities vary on a small length scale and Taylor expansion around the guiding center  $\mathbf{X}$  can not be applied advantageous. Their values have to be taken at the particle position, which is a function of the gyroangle in guiding center coordinates. After this clarification the components of the perturbed Lagrangian in the guiding center phase space can be written as

$$\begin{aligned} \Gamma_{1,X^i} &= \gamma_{1,x^j} \frac{dx^j}{dX^i} & \Gamma_{1,v_{\parallel}} &= 0 \\ \Gamma_{1,\mu} &= \gamma_{1,x^j} \frac{dx^j}{d\mu} & \Gamma_{1,\theta} &= \gamma_{1,x^j} \frac{dx^j}{d\theta} \\ \Gamma_{1,t} &= \gamma_{1,t} . \end{aligned} \quad (33)$$

After inserting the components of the perturbed Lagrangian  $\gamma_1$  and neglecting terms of order  $\rho^2$ , due to gyrokinetic ordering, the perturbed components in the guiding center coordinates can be expressed as

$$\begin{aligned}\Gamma_{1,\mathbf{x}} &\approx Ze\mathbf{A}_1(\mathbf{x}) & \Gamma_{1,v_{\parallel}} &= 0 \\ \Gamma_{1,\mu} &= \frac{Z}{|Z|} \frac{1}{v_{\perp}(\mathbf{X}, \mu)} \mathbf{A}_1(\mathbf{x}) \cdot \mathbf{a}(\theta) & \Gamma_{1,\theta} &= \frac{Z}{|Z|} \frac{2\mu}{v_{\perp}(\mathbf{X}, \mu)} \mathbf{A}_1(\mathbf{x}) \cdot \frac{d\mathbf{a}(\theta)}{d\theta} \\ \Gamma_{1,t} &= -Ze\Phi_1(\mathbf{x}) .\end{aligned} \quad (34)$$

Finally, the fundamental one-form in the guiding center phase space  $\Gamma$  with perturbation can be written as

$$\begin{aligned}\Gamma &= \langle \Gamma_0 \rangle + \Gamma_1 \\ \langle \Gamma_0 \rangle &= (mv_{\parallel} \mathbf{b}(\mathbf{X}) + m\mathbf{u}_0 + Ze\mathbf{A}_0(\mathbf{X})) \cdot d\mathbf{X} + \frac{2\mu m}{Ze} d\theta \\ &\quad - \left( \frac{1}{2}mv_{\parallel}^2 - \frac{1}{2}mu_0^2 + Ze\Phi_0(\mathbf{X}) + \mu B_0(\mathbf{X}) \right) dt \\ \Gamma_1 &= Ze\mathbf{A}_1(\mathbf{x}) \cdot d\mathbf{X} + \frac{Z}{|Z|} \frac{1}{v_{\perp}} \mathbf{A}_1(\mathbf{x}) \cdot \mathbf{a} d\mu + \frac{Z}{|Z|} \frac{2\mu}{v_{\perp}} \mathbf{A}_1(\mathbf{x}) \cdot \frac{d\mathbf{a}}{d\theta} d\theta - Ze\Phi_1(\mathbf{x}) dt .\end{aligned} \quad (35)$$

### 1.4.3 Lagrangian in Gyrocenter Phase Space

The transformation of the guiding center Lagrangian  $\Gamma$  into the Lagrangian in gyrocenter phase space  $\bar{\Gamma}$  aims to remove the gyroangle  $\theta$  dependence resulting from the introduction of fluctuations. To distinguish between the guiding center and the gyrocenter coordinates all quantities associated with the gyrocenter are getting an overbar, i.e.  $\bar{\Gamma}$ . The new set of gyrocenter coordinates are given by  $\{\bar{\mathbf{X}}, \bar{v}_{\parallel}, \bar{\mu}\}$ . Since the derivation of fundamental the one-form in gyrocenter phase space  $\bar{\Gamma}$  uses the Lie transform perturbation method, which is beyond the scopes of this thesis, the reader is referred to the Refs. 3,9 for more details. The Lagrangian in the gyrocenter phase space can be expressed as

$$\begin{aligned} \bar{\Gamma} &= \bar{\Gamma}_0 + \bar{\Gamma}_1 \\ &= (mv_{\parallel} \mathbf{b}_0(\mathbf{X}) + m\mathbf{u}_0 + Ze (\mathbf{A}_0(\mathbf{X}) + \bar{\mathbf{A}}_1(\mathbf{X}))) \cdot d\mathbf{X} + \frac{2\mu m}{Ze} d\theta \\ &\quad - \left( \frac{1}{2} m (v_{\parallel}^2 - u_0^2) + Ze (\Phi_0(\mathbf{X}) + \bar{\Phi}_1(\mathbf{X})) + \mu (B_0(\mathbf{X}) + \bar{B}_{1\parallel}(\mathbf{X})) \right) dt, \end{aligned} \quad (36)$$

where  $B_0$  is the equilibrium magnetic field and  $\bar{B}_{1\parallel}$  is the magnetic field introduced by the vector potential  $\bar{\mathbf{A}}_1$ . Note, that the quantities  $\bar{\Phi}_1$ ,  $\bar{\mathbf{A}}_1$  and  $\bar{B}_{1\parallel}$  are the shorter notation of following gyroaveraged quantities defined as

$$\begin{aligned} \langle \Phi_1(\mathbf{x}) \rangle &= \bar{\Phi}_1(\mathbf{X}) \\ \langle \mathbf{A}_1(\mathbf{x}) \rangle &= \bar{\mathbf{A}}_1(\mathbf{X}) \\ Ze \langle \mathbf{A}_1(\mathbf{x}) \cdot \mathbf{v}_{\perp}(\mathbf{X}, \mu, \theta) \rangle &= \mu \bar{B}_{1\parallel}(\mathbf{X}). \end{aligned} \quad (37)$$

The components of the gyrocenter Lagrangian are again independent of the gyrophase  $\theta$ , and therefore the magnetic moment  $\mu$  remains in the gyrocenter phase space an invariant of motion.

## 1.5 Gyrokinetic Equation

### 1.5.1 Vlasov Equation

Because of the large number of particles in the fusion plasma a prediction on the basis of Newton-Maxwell dynamics results in an impossible task for simulation, but this problem can be solved with a statistical approach. For that the distribution function  $f(\mathbf{x}, \mathbf{v}, t)$  in the particle phase space  $\{\mathbf{x}, \mathbf{v}\}$  will be considered. Because collisions are happening at much smaller frequencies than the characteristic frequencies connected to turbulence, the collisionless model is often preferred<sup>4</sup> which results through evolution of the particle density distribution function in the *Vlasov equation*

$$\frac{\partial f}{\partial t} + \dot{\mathbf{x}} \cdot \frac{\partial f}{\partial \mathbf{x}} + \dot{\mathbf{v}} \cdot \frac{\partial f}{\partial \mathbf{v}} = 0 . \quad (38)$$

To obtain a closed system the Maxwell equations with the particle density  $n$  and current density  $j$  can be described with the distribution function as follows

$$n = \int d\mathbf{v} f(\mathbf{x}, \mathbf{v}, t) \quad j = q \int d\mathbf{v} \mathbf{v} f(\mathbf{x}, \mathbf{v}, t) , \quad (39)$$

which are then substituted into the Maxwell equations

$$\begin{aligned} \nabla \cdot \mathbf{B} &= 0 & \nabla \times \mathbf{B} &= \mu_0 \left( \sum_{\text{species}} j + \epsilon_0 \frac{\partial \mathbf{E}}{\partial t} \right) \\ \nabla \cdot \mathbf{E} &= \frac{1}{\epsilon_0} \sum_{\text{species}} qn & \nabla \times \mathbf{E} &= -\frac{\partial \mathbf{B}}{\partial t} . \end{aligned} \quad (40)$$

The Vlasov equation (38) in combination with the Maxwell equations (39) and (40) is the basis of the gyrokinetic model.<sup>5</sup>

In the gyrocenter phase space  $\{\bar{\mathbf{X}}, \bar{v}_{\parallel}, \bar{\mu}\}$  the Vlasov equation takes following form

$$\frac{\partial f}{\partial t} + \dot{\bar{\mathbf{X}}} \cdot \frac{\partial f}{\partial \bar{\mathbf{X}}} + \dot{\bar{v}}_{\parallel} \cdot \frac{\partial f}{\partial \bar{v}_{\parallel}} = 0 , \quad (41)$$

where the gyrophase  $\theta$  is still an ignorable coordinate and the time derivative of the magnetic moment  $\mu$  is zero, because the magnetic moment  $\mu$  is an exact invariant. In Equation (41) the terms of the time derivative of the gyrocenter  $\dot{\bar{\mathbf{X}}}$  and the parallel velocity  $\dot{\bar{v}}_{\parallel}$  have to be expressed through the gyrocenter Lagrangian with the Euler-Lagrange equation. The Euler-Lagrange equation can be written as

$$\left( \frac{\partial \gamma_j}{\partial z^i} - \frac{\partial \gamma_i}{\partial z^j} \right) \frac{dz^j}{dt} = \frac{\partial H}{\partial z^i} + \frac{\partial \gamma_i}{\partial t} . \quad (42)$$

Inserting Equation (36) into the Euler-Lagrange equation and apply multiple calculations detailed in Ref. 9 the equations of motion can be obtained as

$$\begin{aligned} \dot{\mathbf{X}} &= v_{\parallel} \mathbf{b}_0 + \mathbf{v}_{\chi} + \mathbf{v}_D & \dot{v}_{\parallel} &= \frac{\dot{\mathbf{X}}}{mv_{\parallel}} \cdot (Ze\bar{\mathbf{E}} - \mu\nabla(B_0 + \bar{B}_{1\parallel}) + mR\Omega^2\nabla R) \\ \dot{\mu} &= 0 & \dot{\theta} &= \omega_c - \frac{Ze}{m} \partial_{\mu} \left( Ze\bar{\mathbf{A}}_1 \cdot \dot{\mathbf{X}} - Ze\bar{\Phi}_1 - \mu\bar{B}_{1\parallel} \right) , \end{aligned} \quad (43)$$

with the drift velocity  $\mathbf{v}_{\chi}$  defined as the sum of the streaming velocity perpendicular to the pertubated magnetic field  $\mathbf{v}_{\bar{B}_{1\perp}}$ , the  $\mathbf{E} \times \mathbf{B}$  drift in the total electric field  $\mathbf{v}_{\bar{\mathbf{E}}}$  and the grad- $B$  drift of the parallel perturbed magnetic field  $\mathbf{v}_{\nabla\bar{B}_{1\parallel}}$  and the drift velocity  $\mathbf{v}_D$  containing the sum of the curvature drift  $\mathbf{v}_C$ , the grad- $B$  drift of the equilibrium magnetic field  $\mathbf{v}_{\nabla B_0}$  and the drifts due to the Coriolis force  $\mathbf{v}_{C_0}$  and centrifugal force  $\mathbf{v}_{Cf}$ . Note that the term containing  $u_0^2$  got replaced with Equation (12) and the total electric field  $\bar{\mathbf{E}}$  is defined as

$$\bar{\mathbf{E}} = -\nabla \underbrace{(\Phi_0 + \bar{\Phi}_1)}_{\bar{\Phi}} - \partial_t \bar{\mathbf{A}}_1 \approx -\nabla(\Phi_0 + \bar{\Phi}_1) , \quad (44)$$

since the time derivative is of the vector potential  $\partial_t \bar{\mathbf{A}}_1$  is one order smaller as the gradient of the electrostatic potential  $\nabla \bar{\Phi}$ .

### 1.5.2 The delta- $f$ Approximation

The delta- $f$  approximation separates the density distribution function  $f$  into an equilibrium part  $f_0$  and perturbation part  $f_1$ , i.e.  $f = f_0 + f_1$ . Applying the delta- $f$  approximation on the gyrocenter Vlasov equation leads to

$$\frac{\partial f_1}{\partial t} + \dot{\mathbf{X}} \cdot \nabla f_1 + \dot{v}_{\parallel} \cdot \frac{\partial f_1}{\partial v_{\parallel}} = \underbrace{-\dot{\mathbf{X}} \cdot \nabla f_0 - \dot{v}_{\parallel} \frac{\partial f_0}{\partial v_{\parallel}}}_S, \quad (45)$$

with the source term  $S$ . Substituting from Equation (43) the equations for  $\dot{\mathbf{X}}$  and  $\dot{v}_{\parallel}$  into the delta- $f$  approximated Vlasov equation results in

$$\frac{\partial f_1}{\partial t} + \dot{\mathbf{X}} \cdot \nabla f_1 - \frac{\mathbf{b}_0}{m} \cdot (Ze \nabla \Phi_0 + \mu \nabla B_0 - m R \Omega^2 \nabla R) \cdot \frac{\partial f_1}{\partial v_{\parallel}} = S. \quad (46)$$

Note that only the terms of order  $\rho_{\star}$  has to be kept in  $\dot{v}_{\parallel} \frac{\partial f_1}{\partial v_{\parallel}}$ , which results in neglecting the drift velocities  $\mathbf{v}_{\chi}$  and  $\mathbf{v}_D$  and the contribution of  $\bar{B}_{1\parallel}$  and  $\bar{\Phi}_1$ , since these terms are after calculation of order  $\rho_{\star}^2$ .

The equilibrium distribution function  $f_0$  is assumed to be a Maxwellian which includes a finite equilibrium electric field  $\Phi_0$  to balance the centrifugal force (in the co-rotating frame) due toroidal rotation of the plasma. In the rotating frame the included term can be written as (SOURCE)

$$\mathcal{E} = Ze \langle \Phi_0 \rangle - \frac{1}{2} m \omega_{\varphi}^2 (R^2 - R_0^2), \quad (47)$$

where  $\langle \cdot \rangle$  denote flux-surface averaging,  $\omega_{\varphi}$  the plasma rotation frequency [Eq. (13)],  $R$  the local major radius and  $R_0$  is an integration constant which can be chosen, i.e. major radius of the plasma or flux surface average of the major radius (SOURCE). The Maxwellian is given by the following expression

$$f_0 = f_M(\mathbf{X}, v_{\parallel}, \mu) = \frac{n_0}{(2\pi T/m)^{3/2}} \exp \left( -\frac{\frac{1}{2} m (v_{\parallel} - u_{\parallel})^2 + \mu B_0 + \mathcal{E}}{T} \right), \quad (48)$$

where  $n_0$  is the equilibrium particle density and  $u_{\parallel}$  is the rotation speed of the plasma in the rotating frame parallel to the magnetic field [Eq. (14)]. The derivatives of the Maxwellian can be expressed as (SOURCE)

$$\begin{aligned} \nabla f_M &= \left[ \frac{\nabla n_0}{n_0} + \left( \frac{\frac{1}{2} m v_{\parallel}^2 + \mu B_0 + \mathcal{E}}{T} - \frac{3}{2} \right) \frac{\nabla T}{T} - \frac{\mu B_0}{T} \frac{\nabla B_0}{B_0} \right. \\ &\quad \left. + \left( \frac{m v_{\parallel} R B_t}{B T} + m \omega (R^2 - R_0^2) \right) \nabla \omega_{\varphi} \right] f_M \\ \partial_{v_{\parallel}} f_M &= -\frac{m v_{\parallel}}{T} f_M \\ \partial_{\mu} f_M &= -\frac{B_0}{T} f_M, \end{aligned} \quad (49)$$

where the  $\nabla\omega_{\varphi}$  terms are the result of the derivatives of the parallel rotation velocity  $u_{\parallel}$  and rotation energy  $\mathcal{E}$  evaluated at zero rotation speed locally in the co-rotating frame. It can be shown with Equations (43) and (49) that the  $\nabla B_0$  term in  $-\dot{\mathbf{X}} \cdot \nabla f_M$  cancels with  $(\dot{\mathbf{X}}/mv_{\parallel})\mu\nabla B_0\partial_{v_{\parallel}}f_M$  for purely toroidal rotation. Finally, the source term can than be written as

$$S = -(\mathbf{v}_{\chi} + \mathbf{v}_D) \cdot \tilde{\nabla} f_M - \frac{Zev_{\parallel}}{T} \partial_t \bar{A}_{1\parallel} f_M - \frac{f_M}{T} (v_{\parallel} \mathbf{b}_0 + \mathbf{v}_D + \mathbf{v}_{\bar{B}_{1\perp}}) \cdot (Ze\nabla\bar{\Phi} + \mu\nabla\bar{B}_{1\parallel}) , \quad (50)$$

where  $\tilde{\nabla}$  refers to only the  $\nabla n_0$ ,  $\nabla T$  and  $\nabla\omega_{\varphi}$  terms of  $\nabla f_M$ .

In Equation (50) the appearance of the term of the perturbed vector potential  $\bar{A}_{1\parallel}$  is computationally difficult to evaluate. To avoid further complications a modified distribution function  $g$  will be introduced as

$$g = \delta f + \frac{Zev_{\parallel}}{T} \bar{A}_{1\parallel} f_M . \quad (51)$$

Substituting the modified distribution function  $g$  into Equation (46) results in

$$\frac{\partial g}{\partial t} + \mathbf{v}_{\chi} \cdot \nabla g + (v_{\parallel} \mathbf{b}_0 + \mathbf{v}_D) \cdot \nabla f_1 - \frac{\mathbf{b}_0}{m} \cdot (Ze\nabla\Phi_0 + \mu\nabla B_0 - mR\Omega^2\nabla R) \frac{\partial f_1}{\partial v_{\parallel}} = S \quad (52)$$

$$S = -(\mathbf{v}_{\chi} + \mathbf{v}_D) \cdot \tilde{\nabla} f_M + \frac{f_M}{T} (v_{\parallel} \mathbf{b}_0 + \mathbf{v}_D) \cdot (-Ze\nabla\bar{\Phi}_1 - \mu\nabla\bar{B}_{1\parallel}) . \quad (53)$$

This is the for of the Vlasov equation currently implemented in GKW (SOURCE) and which will be further modified in the course of this thesis.
